Lecture 4: Scalar-tensor theories and dark energy

Shinji Tsujikawa
(Tokyo University of Science)
Fields relevant to dark energy

In the standard model of particle physics and cosmology, the most studied fields (which are massive) are spin 0, 1, and 2.

- **Spin 0**
  - Scalar $\phi$
  - Lagrangian: $\mathcal{L} = -\frac{1}{2} (\partial \phi)^2 - V(\phi)$

- **Spin 1**
  - Vector $A_\mu$
  - Lagrangian: $\mathcal{L} = -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} - m^2 A_\mu A^\mu$

- **Spin 2**
  - Tensor $g_{\mu\nu}$
  - Lagrangian: $\mathcal{L} = \sqrt{-g} R - m^2 \mathcal{U}(g, f)$

**Coupling to gravity**

- Scalar-tensor theories (including minimally coupled scalar: quintessence)
- Vector-tensor theories
- Massive gravity
Ostrogradski instability

The theories whose equations of motion contain time derivatives higher than second order are generally prone to an Ostrogradski instability.

Consider the Lagrangian of harmonic oscillator with an additional $\alpha \ddot{q}^2$ term in the Minkowski space-time:

$$L = \frac{1}{2} m \dot{q}^2 - \frac{1}{2} m \omega^2 q^2 + \alpha \ddot{q}^2$$

The Euler-Lagrange equation is

$$\frac{\partial L}{\partial q} - \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}} \right) + \frac{d^2}{dt^2} \left( \frac{\partial L}{\partial \ddot{q}} \right) = 0$$

For $\alpha \neq 0$, this equation contains derivatives higher than second order.

The Hamiltonian is given by

$$\mathcal{H} = \frac{1}{2} m \dot{q}^2 + \frac{1}{2} m \omega^2 q^2 + \alpha \ddot{q}^2 - 2 \alpha \dot{q} \ddot{q}$$

This term leads to an instability associated with the Hamiltonian unbounded from below (Ostrogradski instability).
Second-order scalar theories on Minkowski (spin 0 case)

For the scalar field $\phi$ it is possible to construct the Lagrangian which gives rise to the second-order equations of motion:

$$\mathcal{L}_2 = g_2(\phi, X),$$
$$\mathcal{L}_3 = g_3(\phi, X) \Box \phi,$$
$$\mathcal{L}_4 = g_4(\phi, X) \left[ (\Box)^2 - \partial^\mu \partial^\nu \phi \partial_\mu \partial_\nu \phi \right],$$
$$\mathcal{L}_5 = g_5(\phi, X) \left[ (\Box)^3 - 3(\partial_\mu \partial_\nu \phi)(\partial^\mu \partial^\nu \phi) \Box \phi + 2\partial^\mu \partial_\nu \phi \partial^\nu \partial_\lambda \phi \partial_\lambda \partial^\mu \phi \right].$$

where $g_{2,3,4,5}$ are functions of $\phi$ and $X = -\partial_\mu \phi \partial^\mu \phi / 2$.

These Lagrangians can be expressed as

$$\mathcal{L}_N = g_N(\phi, X) \mathcal{E}_{N-1},$$

where

$$\mathcal{E}_N = -\mathcal{B}_{(2n+2)}^{\mu_1 \cdots \mu_n+1 \nu_1 \cdots \nu_{n+1}} \partial_{\mu_1} \partial_{\nu_1} \phi \cdots \partial_{\mu_n} \partial_{\nu_n} \phi \partial_{\mu_{n+1}} \partial_{\nu_{n+1}} \phi$$

(with $N = n + 2$)

with

$$\mathcal{B}_{(2n)}^{\mu_1 \cdots \mu_n \nu_1 \cdots \nu_n} = \frac{1}{(4 - n)!} \varepsilon^{\mu_1 \cdots \mu_n \lambda_1 \cdots \lambda_{4-n}} \varepsilon^{\nu_1 \cdots \nu_n \lambda_1 \cdots \lambda_{4-n}}$$

The anti-symmetric property of the Levi-Civita tensor $\varepsilon^{\mu \nu \rho \sigma}$ allows to eliminate derivatives higher than second order from the EOM.
Coupling to gravity

If we try to construct second-order theories in the presence of gravity, the situation is more involved.

Replacing partial derivatives of the second-order Lagrangians $\mathcal{L}_4$, $\mathcal{L}_5$ with covariant derivatives, it gives rise to derivatives higher than second order.

\[ \mathcal{L}_4 = g_4(\phi, X) \left[ (\Box \phi)^2 - \nabla^\mu \nabla^\nu \phi \nabla_\mu \nabla_\nu \phi \right] \]

\[ \mathcal{L}_5 = g_5(\phi, X) \left[ (\Box \phi)^3 - 3(\nabla_\mu \nabla_\nu \phi)(\nabla^\mu \nabla^\nu \phi) + 2\nabla^\mu \nabla_\nu \phi \nabla^\nu \nabla_\lambda \phi \nabla^\lambda \nabla_\mu \phi \right] \]

(theories higher than second order)

For $\mathcal{L}_4$ it is possible to eliminate derivatives higher than second order by adding the non-minimal coupling $G_4(\phi, X)R$ with the replacement $g_4(\phi, X) \rightarrow G_{4,X} \equiv \partial G_4 / \partial X$ (where $R$ is the Ricci scalar).

For $\mathcal{L}_5$ we can also eliminate derivatives higher than second order by adding the gravitational coupling $G_5(\phi, X)G_{\mu\nu} \nabla^\mu \nabla^\nu \phi$ with the replacement $g_5(\phi, X) \rightarrow -G_{5,X} / 6$ (where $G_{\mu\nu}$ is the Einstein tensor).

Known as Horndeski theories
Horndeski theories: most general scalar-tensor theories with second-order equations of motion

Horndeski action: \[ S = \int d^4x \sqrt{-g} L \]

with the Lagrangian

\[
L = G_2(\phi, X) + G_3(\phi, X) \Box \phi + G_4(\phi, X) R + G_{4,x}(\phi, X) \left[ (\Box \phi)^2 - (\nabla_\mu \nabla_\nu \phi)(\nabla^\mu \nabla^\nu \phi) \right] + G_5(\phi, X) G_{\mu\nu} \nabla^\mu \nabla^\nu \phi - \frac{1}{6} G_{5,x}(\phi, X) \left[ (\Box \phi)^3 - 3(\Box \phi) (\nabla_\mu \nabla_\nu \phi)(\nabla^\mu \nabla^\nu \phi) + 2(\nabla^\mu \nabla_\alpha \phi)(\nabla^\alpha \nabla_\beta \phi)(\nabla^\beta \nabla_\mu \phi) \right]
\]

This action covers most of the single-field inflation and dark energy models proposed in literature.

- **LCDM**: \( G_2 = -\Lambda, \ G_3 = 0, \ G_4 = M_{\text{pl}}^2/2, \ G_5 = 0 \)
- **Quintessence and K-essence**: \( G_2 = G_2(\phi, X), \ G_3 = 0, \ G_4 = M_{\text{pl}}^2/2, \ G_5 = 0 \)
- **f(R) gravity and scalar-tensor gravity**: \( G_4 = F(\phi), \ G_3 = 0, \ G_5 = 0 \)
- **Galileons**: \( G_2 = -c_2 X, \ G_3 = c_3 X/M^3, \ G_4 = M_{\text{pl}}^2/2 - c_4 X^2/M^6, \ G_5 = 3c_5 X^2/M^9 \)
- **Gauss-Bonnet coupling** \( \xi(\phi)G \) :
  \[
  G_2 = 8\xi^{(4)}(\phi) X^2 (3 - \ln X), \quad G_3 = 4\xi^{(3)}(\phi) X (7 - 3 \ln X) \\
  G_4 = 4\xi^{(2)}(\phi) X (2 - \ln X), \quad G_5 = -4\xi^{(1)}(\phi) \ln X
  \]
Horndeski’s paper in 1973 (age 25)

When Horndeski was the PhD student of David Lovelock, he wrote this valuable paper.

Second-Order Scalar-Tensor Field Equations in a Four-Dimensional Space

GREGORY WALTER HORNDESKI

Department of Applied Mathematics, University of Waterloo, Waterloo, Ontario, Canada

Received: 10 July 1973

Abstract

Lagrange scalar densities which are concomitants of a pseudo-Riemannian metric-tensor a scalar field and their derivatives of arbitrary order are considered. The most general second-order Euler–Lagrange tensors derivable from such a Lagrangian in a four-dimensional space are constructed, and it is shown that these Euler–Lagrange tensors may be obtained from a Lagrangian which is at most of second order in the derivatives of the field functions.

After 1981, Horndeski became an artist.

September 10, 2016

Now, Horndeski wants to construct scalar-tensor theories with third-order equations of motion.

Without taking care of the Ostrogradski instability…
Friedmann equations on the flat FLRW background

\[ S = \int d^4x \sqrt{-g} \left[ G_2(\phi, X) + G_3(\phi, X)\Box \phi + L_4 + L_5 \right] + S_m + S_r \]  

(Horndeski’s action)

Non-relativistic matter

Radiation

The background equations of motion are

\[ 3M_{\text{pl}}^2 H^2 = \rho_{\text{DE}} + \rho_m + \rho_r \]
\[ -2M_{\text{pl}}^2 \dot{H} = \rho_{\text{DE}} + P_{\text{DE}} + \rho_m + 4\rho_r / 3 \]

\( \rho_{\text{DE}} \) and \( P_{\text{DE}} \) are the density and pressure of the “dark” component.

\[
\rho_{\text{DE}} = 3H^2 \left( M_{\text{pl}}^2 - 2G_4 \right) - G_2 + \dot{\phi}^2 G_{2,X} - \ddot{\phi}^2 \left( 3H \dot{\phi} G_{3,X} - G_{3,\phi} \right) - 6H \dot{\phi} \left( G_{4,\phi} + \dot{\phi}^2 G_{4,\phi} \right) \\
-2H \dot{\phi} G_{4,X} - H \ddot{\phi}^3 G_{4,XX} \right) - H^2 \dot{\phi}^2 \left( 9G_{5,\phi} + 3\dot{\phi}^2 G_{5,\phi} - 5H \dot{\phi} G_{5,X} - H \ddot{\phi}^3 G_{5,XX} \right)
\]

The equation of state of dark energy is given by

\[ w = P_{\text{DE}} / \rho_{\text{DE}} \]

The evolution of \( w \) is different depending on dark energy models.

Different models can be distinguished from SNIa, CMB, and BAO data.
Discrimination of models from scalar perturbations

In order to place constraints on dark energy models from the observations of large-scale structure, weak lensing, CMB (ISW effect) etc, we need to study the evolution of scalar density perturbations.

Perturbed metric: \[ ds^2 = -(1 + 2\Psi)dt^2 + a^2(t)(1 + 2\Phi)\delta_{ij}dx^i dx^j \]

Non-relativistic matter: \[ \rho_m = \rho_m(t) + \delta\rho_m(t, x) \]

with the four velocity \[ u^\mu = (1 - \Psi, \nabla^i \nu) \]

\( \nu \) is the rotational-free velocity potential.
Density perturbations in the Horndeski’s theory

\[ \delta \equiv \delta \rho_m / \rho_m \quad \text{and} \quad \theta \equiv \nabla^2 v \quad \text{obey} \quad (\text{in Fourier space with the comoving wavenumber } k) \]

\[
\begin{align*}
\dot{\delta} &= -\theta / a - 3\dot{\Phi} \\
\dot{\theta} &= -H\theta + (k^2 / a)\Psi
\end{align*}
\]

The growth rate of matter perturbations is related with the peculiar velocity.

We introduce the gauge-invariant density contrast:

\[ \delta_m \equiv \delta + \frac{3aH}{k^2} \theta \]

The gravitational potential \( \Psi \) is generally related to \( \delta \rho_m \), as

\[ \frac{k^2}{a^2} \Psi = -4\pi G\mu \delta \rho_m \]

In GR \( \mu = 1 \), but in Horndeski theories \( \mu \) is generally different from 1.

The matter density contrast \( \delta_m \) obeys

\[ \ddot{\delta}_m + 2H\dot{\delta}_m - 4\pi \mu G\rho_m \delta_m \sim 0 \]

Different models can be distinguished from different evolution of \( \delta_m \).
**Lensing gravitational potential**

To characterize the bending of light rays in CMB and weak lensing observations, we define the lensing potential

\[ \psi_{\text{eff}} = \Phi - \Psi \]

This is related to the matter perturbation, as

\[ \frac{k^2}{a^2} \psi_{\text{eff}} = 8\pi G \Sigma \delta \rho_m \]

In GR \( \Sigma = 1 \), but in Horndeski theories \( \Sigma \) is generally different from 1.

**What are the values of \( \mu \) and \( \Sigma \) in Horndeski theories?**

This was generally derived by De Felice, Kobayashi, S.T. (2011), see also 1809.08735.
Quasi-static approximation

Under the quasi-static approximation under which the dominant contributions to the perturbation equations are those containing $k^2$ and $\delta \rho_m$, we obtain

$$\mu = \frac{c_t^2}{8\pi G q_t} \left( 1 + \frac{q_t \Delta_1^2}{c_t^2 \Delta_2} \right)$$

\[
\begin{align*}
\Delta_1 &\equiv c_t^2 (1 + \alpha_B) - 1 - \alpha_M \\
\Delta_2 &\equiv \frac{\phi^2 q_s c_s^2}{4 H^2 q_t} \left( 1 + \frac{2 a^2 M^2_{\phi q_t}}{c_s^2 k^2 q_s} \right)
\end{align*}
\]

Arising from tensor perturbations

Scalar-matter interactions

Under the absence of ghosts and Laplacian instabilities of scalar and tensor perturbations, the gravitational interaction felt by matter is always enhanced.

$$\mu > \frac{c_t^2}{8\pi G q_t}$$

The expression of $\Sigma$ is

$$\Sigma = \frac{1 + c_t^2}{16\pi G q_t} \left[ 1 + \frac{q_t (\alpha_B + \Delta_1) \Delta_1}{(1 + c_t^2) \Delta_2} \right]$$

This can be larger or smaller than 1.
Gravitational-wave propagation in Horndeski theories

\[ ds^2 = -dt^2 + a^2(t)(\delta_{ij} + h_{ij})dx^i dx^j \]

Tensor perturbations obeying \( h^i_c = 0, \quad \partial^i h_{ij} = 0 \)

We can choose the nonvanishing components:

\[ h_{11} = h_1(t, z), \quad h_{22} = -h_1(t, z), \quad h_{12} = h_{21} = h_2(t, z) \]

The second-order action of Horndeski theories expanded up to second order is

\[
S^{(2)}_t = \int dt d^3x \sum_{i=1}^2 \frac{a^3}{4} q_t \left[ \dot{h}_i^2 - \frac{c_t^2}{a^2} (\partial h_i)^2 \right]
\]

where

\[
\begin{align*}
q_t &= 2G_4 - 2\dot{\phi}^2 G_{4,x} + \dot{\phi}^2 G_{5,\phi} - H\dot{\phi}^3 G_{5,x} > 0 \text{ to avoid ghosts} \\
c_t^2 &= \frac{1}{q_t} \left( 2G_4 - \dot{\phi}^2 G_{5,\phi} - \dot{\phi}^2 \ddot{\phi} G_{5,x} \right) > 0 \text{ to avoid Laplacian instability}
\end{align*}
\]

Here, \( c_t \) correspond to the propagation speed of gravitational waves.
Gravitational wave speed constraints on dark energy

The gravitational-wave event GW170817 constrained the speed of gravitational waves to be very close to that of light.

\[-3 \times 10^{-15} \leq \frac{c_t}{c} - 1 \leq 7 \times 10^{-16}\]

while

\[
c_t^2 = \frac{2G_4 - \dot{\phi}^2G_{5,\phi} - \phi^2\ddot{\phi}G_{5,X}}{2G_4 - 2\dot{\phi}^2G_{4,X} + \phi^2G_{5,\phi} - H\phi^3G_{5,X}}
\]

in Horndeski theories

\[
L = G_2(\phi, X) + G_3(\phi, X)\Box\phi + G_4(\phi, X)R - 2G_4,X(\phi, X)[(\Box \phi)^2 - \phi^{\mu\nu\mu\nu}\phi_{\mu\nu}] \\
+ G_5(\phi, X)G_{\mu\nu}\phi^{\mu\nu} + \frac{1}{3}G_5,X(\phi, X)[(\Box \phi)^3 - 3(\Box \phi)\phi_{\mu\nu}\phi^{\mu\nu} + 2\phi_{\mu\nu}\phi^{\mu\nu}\phi'^{\nu}\phi';\sigma]
\]

If we strictly demand

\[c_t = c\]

\[
L = G_2(\phi, X) + G_3(\phi, X)\Box\phi + G_4(\phi)R
\]

Quintessence, K-essence

Cubic Galileons

Brans-Dicke theory, f(R) gravity

In the following, let’s focus on this reduced Lagrangian.

\[G_4 = \frac{M_{pl}^2}{2} \text{ in GR}\]
Brans-Dicke (BD) theory (1961)

Lagrangian: \[ L = \frac{M_{\text{pl}}^2}{2} F(\phi) R + (1 - 6Q^2) F(\phi) X \]

where \[ F(\phi) = e^{-2Q\phi/M_{\text{pl}}} \]

The constant \( Q \) characterizes the coupling between the scalar field \( \phi \) and matter in the Einstein frame. It is related to the BD parameter \( \omega_{\text{BD}} \), as

\[ Q^2 = \frac{1}{2(3 + 2\omega_{\text{BD}})} \]

GR is recovered for \( \omega_{\text{BD}} \to \infty \) i.e., \( Q \to 0 \)

The coupling \( Q \) mediates fifth forces. The solar system experiment gives

\[ \omega_{\text{BD}} > 40000 \quad \Rightarrow \quad |Q| < 2.4 \times 10^{-3} \]

For \( |Q| > 2.4 \times 10^{-3} \), we need some screening mechanism of fifth forces. Two examples are

1. **Chameleon mechanism**: Based on the scalar potential \( V(\phi) \)
   
e.g., \( f(R) \) gravity

2. **Vainshtein mechanism**: Based on the derivative coupling \( G_3(X) \Box \phi \)
   
e.g., Cubic Galileon \( X \Box \phi \)
**f(R) gravity (chameleon mechanism)**

The $f(R)$ gravity is equivalent to BD theories with $Q = -1/\sqrt{6}$ in the presence of a scalar potential:

$$V = \frac{M_{\text{pl}}^2}{2} \left( R \frac{\partial f}{\partial R} - f \right)$$

with the scalar degree of freedom (scalaron):

$$\phi = \sqrt{\frac{3}{2}} M_{\text{pl}} \ln \frac{\partial f}{\partial R}$$

As long as the form of $f(R)$ is designed to have a large mass in regions of high density, the chameleon mechanism is at work.

**Example:**

$$f(R) = R - \lambda R_0 \frac{(R/R_0)^{2n}}{(R/R_0)^{2n} + 1}$$  
(Hu and Sawicki, 2007)

In the high-density region ($R \gg R_0$), the scalaron mass squared grows as

$$M_{\phi}^2 = \frac{d^2V}{d\phi^2} \propto R^{2(n+1)} \gg H^2$$

The field is very heavy, so the propagation of fifth forces is suppressed.
**f(R) dark energy**

The models are constructed to recover the $\Lambda$CDM behavior in the past.

\[
f(R) = R - \lambda R_0 \frac{(R/R_0)^{2n}}{(R/R_0)^{2n} + 1}
\]

\[f(R) = R - \lambda R_0 \quad \text{for} \quad R \gg R_0\]

After $R$ decreases to the order of $R_0$, the model deviates from the $\Lambda$CDM.

**Deviation parameter from the $\Lambda$CDM:**

\[B = \frac{R f_{,RR}}{f_{,R}} \frac{H \dot{H}}{\dot{H} R}
\]

\[B < 1.1 \times 10^{-3} \quad \text{today}
\]

Lombriser et al (2012)

To avoid the large enhancement of perturbations at the late cosmological epoch ($G_{\text{eff}} = 4G/3$).

The variation of $w$ at low redshifts is also limited:

\[|w + 1| < \mathcal{O}(0.01)
\]

Battye et al (2018)

Indistinguishable from the $\Lambda$CDM in current observations.
Cubic Galileons (Vainshtein mechanism)

\[ L = X - m^3 \phi + \frac{\beta_3}{M^3} X \Box \phi + \frac{M_{\text{pl}}^2}{2} e^{-2Q\phi/M_{\text{pl}}} R \]

where

\[ M = (M_{\text{pl}}H_0^2)^{1/3} \approx 10^{-22} \text{ GeV} \]

Around a local source with the Schwarzschild radius \( r_g \), the scalar-matter coupling is suppressed within the Vainshtein radius:

\[ r_V = (|\beta_3 Q|r_gH_0^2)^{1/3} \]

As long as

\[ |\beta_3 Q| \gg 10^{-17} \]

the firth force is suppressed inside the solar system.

Line element:

\[ ds^2 = -(1 + 2\Psi) dt^2 + (1 + 2\Phi) a^2(t) \delta_{ij} dx^i dx^j \]

Inside the Vainshtein radius,

\[ -\Psi \simeq \Phi \simeq \frac{G_N M}{r} \left[ 1 + \mathcal{O}(1) Q^2 \left( \frac{r}{r_V} \right)^{3/2} \right] \]

where

\[ G_N = \frac{1}{8\pi M_{\text{pl}}^2 F'(\phi)} \]

suppressed for \( r \ll r_V \)

Inheriting the time dependence of dark energy scalar field
The recent LLR bound on the time variation of $G_N$ today is

$$\frac{\dot{G}_N}{G_N} = (7.1 \pm 7.6) \times 10^{-14} \text{ yr}^{-1}$$

Tighter than the previous one by one order of magnitude

Nonminimally coupled theories:

$$G_N = \frac{1}{8\pi M_{pl}^2 F(\phi)}$$

$$\frac{\dot{G}_N}{G_N} = -\frac{\dot{F}}{F}$$

The Vainshtein mechanism does not screen the time variation of $G_N$.

Defining $\alpha_M \equiv \frac{\dot{F}}{HF} = -\frac{2Q\dot{\phi}}{HM_{pl}}$, today’s LLR bound translates to

$$-2.05 \times 10^{-3} \left( \frac{0.7}{h} \right) \leq \alpha_M(t_0) \leq 0.07 \times 10^{-3} \left( \frac{0.7}{h} \right)$$

where $H_0 = 100 \ h \ \text{km s}^{-1} \ \text{Mpc}$ is today’s Hubble expansion rate.

This strongly limits the time variation of the dark energy field $\phi$ nonminimally coupled to gravity.
Constraints on the nonminimal coupling of cubic Galileons

\[ L = X - m^3 \phi + \frac{\beta_3}{M^3} X \Box \phi + \frac{M_{\text{pl}}^2}{2} e^{-2Q \phi / M_{\text{pl}}} R \]

- For \(|\beta_3| \ll 1\), the matter era is replaced by the \(\phi\)MDE in which the field kinetic energy dominates the scalar field dynamics.

\[ \alpha_M \simeq 4Q^2 < 0.07 \times 10^{-3} \quad \Rightarrow \quad |Q| < 4.2 \times 10^{-3} \]

On using today’s bound \(\alpha_M(t_0) < 0.07 \times 10^{-3}\), the bound is even tighter:

\[ |Q| < 3.4 \times 10^{-3} \quad \Rightarrow \quad \text{Almost close to the bound } |Q| < 2.4 \times 10^{-3} \]

derived without the Vainshtein screening.

- For \(|\beta_3| \gg 1\), the \(\phi\)MDE is not present and the field kinetic energy is strongly suppressed due to the cosmological Vainshtein screening.

\[ |Q| \text{ is not strongly constrained, but the time variation of } \phi \text{ is very tiny.} \]

\[ \text{The nonminimal coupling } F(\phi) = e^{-2Q\phi / M_{\text{pl}}} \text{ is very close to 1.} \]
Modified gravitational wave (GW) propagation

In nonminimally coupled theories, tensor perturbations obey

\[ \ddot{h}_{ij} + H (3 + \alpha_M) \dot{h}_{ij} + \frac{k^2}{a^2} h_{ij} = 0 \]

Modified from GR

The GW and luminosity distances are different:

\[ d_{GW}(z) = \frac{d_L(z)}{\sqrt{F(z)}} \]

\[ \frac{d_{GW}(z)}{d_L(z)} - 1 \lesssim \frac{\alpha_{\text{max}}}{2} \ln(z + 1) \lesssim 3.5 \times 10^{-5} \ln (1 + z) \]

LLR bound: \( \alpha_{\text{max}} = 0.07 \times 10^{-3} \)

The upper bound is determined by the value of \( \alpha_M \) around \( z \lesssim 1 \), so that

\[ \frac{d_{GW}(z)}{d_L(z)} - 1 \lesssim \mathcal{O}(10^{-5}) \quad \text{for} \quad 0 < z < 100 \]
Model: \[ L = X - m^3 \phi + \frac{\beta_3}{M^3} X \Box \phi + \frac{M^2_{\text{pl}}}{2} e^{-2Q\phi/M_{\text{pl}}^1} R \]

In both cases, \[ \frac{d_{\text{GW}}(z)}{d_L(z)} - 1 \lesssim \mathcal{O}(10^{-5}) \]

\[\alpha_M(t_0) \simeq 0.07 \times 10^{-3}\] in these four cases

Smaller \( \alpha_M(t_0) \)

Difficult to distinguish two distances observationally under the LLR bound
**Minimally coupled cubic Horndeski theories**

If we do not observe any signatures of nonminimal couplings, the left-over Horndeski Lagrangian is

\[
L = G_2(\phi, X) + G_3(\phi, X) \Box \phi + \frac{M_{\text{pl}}^2}{2} R
\]

There are three possibilities (in the presence of cubic Lagrangian):

(A) **Galileons without a potential:**

\[
L = X + \frac{\beta_3}{M^3} X \Box \phi + \frac{M_{\text{pl}}^2}{2} R
\]

There exists the self-accelerating solution with \( \dot{\phi} = \text{constant} \).

(B) **Galileons with a potential:**

\[
L = X - V(\phi) + \frac{\beta_3}{M^3} X \Box \phi + \frac{M_{\text{pl}}^2}{2} R
\]

Galileon has a linear potential \( V(\phi) = m^3 \phi \) driving cosmic acceleration.

(C) **Galileons with k-essence:**

\[
L = G_2(X) + \frac{\beta_3}{M^3} X \Box \phi + \frac{M_{\text{pl}}^2}{2} R
\]

For example, the ghost condensate \( G_2(X) = -X + c_2 X^2 \) leads to the dark energy dynamics different from case (A).
(A) Galileons without a potential

Lagrangian: \[ L = X + \frac{\beta_3}{M^3} X \Box \phi + \frac{M^2_{\text{pl}}}{2} R \]

There is a tracker solution along which \( w = -2 \) in the matter era (finally approaching \( w = -1 \)).

Disfavored from the CMB+BAO+SNe data

The cosmic growth history of Galileons is also in tension with the observational data of redshift-space distortions, weak lensing, and ISW-galaxy cross-correlations.

De Felice and ST (2010)
Nesseris, De Felice, ST (2010)
Renk et al (2016)
(B) Galileons with a potential

\[ L = X - V(\phi) + \frac{\beta_3}{M^3} X \Box \phi + \frac{M_{pl}^2}{2} R \]

Provided the potential \( V(\phi) \) of a light scalar dominates over the Galilein term at late times, the model is observationally allowed.

Bound on today’s Galileon density parameter: \( \Omega_{G_3}(t_0) < 0.2 \)

For \( \beta_3 > 1 \), the Galileon term can suppress the field kinetic energy such that \( \Omega_K \ll \Omega_{G_3} \ll \Omega_V = \mathcal{O}(1) \) today.

Even for \( \lambda \equiv M_{pl} V,\phi/V > 1 \), the dark energy equation of state quickly approaches \(-1\) after the dominance of \( \Omega_V \) (with \( w_{DE} > -1 \)).

It deserves for further study to find the allowed parameters space of \( \beta_3 \) and \( \lambda \).
(C) Galileon ghost condensate (GGC)  

\[ L = X + c_2 X^2 + \frac{\beta_3}{M^3} \square \phi + \frac{M_{\text{pl}}^2}{2} R \]

This term prevents the approach to tracker solutions \((w_{\text{DE}} = -2)\).

Moreover, the growth perturbations can be close to that in GR \((\mu = \Sigma = 1)\).

There should be an observational lower bound on \(c_2\) (under consideration).
According to the joint analysis of SN Ia, CMB, BAO, and RSD data, GGC is statistically favored over the LCDM.

At the background, $w_{DE}$ is in the range $-2 < w_{DE} < -1$.

The large-scale CMB spectrum is suppressed relative to that in LCDM.

Better compatibility with the Planck CMB data

Alleviating the problem of tracker solutions of Galileons
Observational constraints on GGC

$\chi^2$, $c_2X^2$, and $\beta_3\Box\phi/M^3$, respectively.

Not only the $\chi^2$ statistic but also several information criteria (like the Bayesian evidence) support GGC over LCDM (in spite of two additional parameters).
Summary of scalar-tensor dark energy models

The GW170817 event constrained the Hordenski Lagrangin to be

\[ L = G_2(\phi, X) + G_3(\phi, X)\Box\phi + G_4(\phi)R \]

- Quintessence and k-essence are not particularly favored over LCDM from the current observational data.
- So far, there were no observational signatures for nonminimally coupled theories (including \( f(R) \) gravity).
- The cubic Galileon with the late-time dominance as dark energy is ruled out from observations.
- However, the GGC model is in a better compatibility with the data in comparison to LCDM.

Let’s see how future observational data constrain the GGC model further.
